Decision Criteria¹ QuickSheet²

Decision Criteria are those elements to be considered when seeking to choose from a selection of potential investment projects and generally include the following:

- Net Present Value (NPV)
- Present Value (PV)
- Internal Rate of Return (IRR)
- Modified Internal Rate of Return (MIRR)
- Profit Index
- Payback Period
- Discounted Payback Period

	The Net Present Value (NPV) of a project or transaction is the		
	present value of the expected future cash flows, discounted		
	for rate and time, less the present value of the costs or		
	investment required to acquire the investment. We most		
	often compare the NPV to 0 when we're considering NPV as		
	one of the Decision Criteria . If a project has an NPV = 0, then		
$\sum Cash Flows_i \sum Costs_i$	the project's internal rate of return (IRR) is equal to the		
$NPV = \sum \frac{Cash Flows_i}{(1+r)^t} - \sum \frac{Costs_i}{(1+r)^t}$	discount rate (expected rate of return) used in the		
	estimation. If the NPV is greater than 0, the IRR is greater		
	than the discount rate, and if the NPV is less than 0 the IRR is		
	less than the discount rate. It's important to note that when		
	the NPV is 0, the investors have earned a return equal to the		
	discount – the rate they expected to earn. It does not mean		
	they have not earned a return.		
	The Present Value (PV) of a project or transaction is the		
	present value of the expected future cash flows, discounted		
$PV = \sum \frac{Cash \ Flows_i}{(1+r)^t}$	for rate and time. It is the value of the project or investment		
	or the price that must be paid to acquire the investment. If		
	an investor does not have the ability to come up with the		
	required amount, PV becomes one of the Decision Criteria .		
	The Internal Rate or Return (IRR) is the actual return an		
	investor may expect to receive given a set of expected future		
IRR – there is no single equation for IRR	cash flows and costs based on the assumption that excess		
MN - there is no single equation for inv	cash flows. It is calculated via an iterative process resulting in		
	a rate and includes the effect of reinvesting excess cash flows		
	at the calculated rate. Even though an investor may have a		

¹ The Decision Criteria QuickSheet is intended to present an abbreviated presentation of the included concepts in corporate finance and is not intended to be a full or complete representation of the concepts, models, metrics or the underlying foundations from which they are built.

	stated discount rate (enpertunity sest of sanital they may		
	stated discount rate (opportunity cost of capital, they may		
	also have a required IRR that may or may not be the same as		
	the discount rate. Used in this manner, IRR becomes one of		
	the Decision Criteria.		
	The Modified Internal Rate of Return (MIRR) is the expected		
	return an investor may expect to receive given a set of		
$\mathbf{MIRR} = \sqrt[n]{\frac{Future\ Value\ of\ Future\ Cash\ Flows}{Present\ Value\ of\ Costs}} - 1$	expected future cash flows and costs based on the		
$\sqrt{\qquad}$ Present Value of Costs	assumption that excess cash flows are reinvested at the		
	investor's discount rate. It is useful as one of the Decision		
	Criteria in the same way IRR is useful.		
	The Profit Index is a ratio of the present value of an asset's		
	expected future cash flows compared to the present value of		
	the costs one might be required to pay to acquire it, or		
	acquire a stake in it. When considered as one of the Decision		
Profit Index =	Criteria the value of this index is often compared to 1, or the		
Present Value of Future Cash Flows Present Value of Costs	index at which the present value of the future cash flows is		
Present value of Costs	equal to the present value of the expected costs. An index of		
	greater than one infers an NPV greater than 0; an index of		
	less than 1 suggests and NPV less than 0, and an index value		
	equal to 1 infers and NPV equal to 0.		
	The Payback Period is the number of periods required for an		
	investor to recoup their cost for an investment or project		
	given the nominal value of its estimated future cash flows.		
\(\sigma_{\cont}\)	The equation shown gives the average Payback period, but a		
Payback Period = $\frac{\sum Costs}{\sum Future\ Cash\ Flows}$	more rigorous assessment may reveal a somewhat different		
# Periods	outcome when specific periodic cash flows are taken into		
	consideration. Payback Period is useful as one of the		
	Decision Criteria as an investor may require they receive a		
	return of their investment within a certain time frame.		
	The Discounted Payback Period is the number of periods		
	required for an investor to recoup their cost for an		
	investment or project given the present value of its estimated		
Discounted Payback Period $ = \frac{\sum Costs}{\sum Discounted Future Cash Flows} $	future cash flows (discounted cash flows). The equation		
	shown gives the average Discounted Payback Period , but a		
	more rigorous assessment may reveal a somewhat different		
	outcome when specific periodic cash flows are taken into		
	consideration. Discounted Payback Period is useful as one of		
	the Decision Criteria as an investor may require they receive		
	a return of their investment within a certain time frame.		

Decision Criteria

Each of the **Decision Criteria** are helpful for investors and managers to objectively make a decision in the face of sometimes disparate costs, cash flows, and discount rates represented by multiple projects or investment options. Here's an example. Suppose you have to consider between three different projects in which your firm may choose to invest: Project 1) put in place a new production line at a cost of \$750,000 with expected future

cash flows of \$65,000 annually; Project 2) invest in a sales and marketing campaign at a cost of \$800,000 projected to increase total revenues by 7%, or Project 3) purchase a new work flow and operations management software suite at a cost of \$600,000 that promises to decrease costs by 2%. Given enough additional information we can identify the change in the firm's cash flows in each case. We can also assign a reasonable discount rate for each project reflective of the firm's cost of capital and possibly make some adjustment based on the likelihood the expected cash flows will materialize. With these data we can then calculate the PV, NPV, IRR, Profit Index, Payback Period and Discounted Payback Period for each project and then use these instruments to help us make our investment decision.

NPV, IRR and Profit Index Relationship

When we think about NPV, IRR and Profit Index we see they're related values as follows. Knowing this helps us apply the Decision Criteria and make the project selection that best suits our investment needs.

NPV	IRR	Profit Index
> 0	> r	>1
= 0	= r	= 1
< 0	< r	< 1

Nominal Profit vs. Economic Profit

Suppose we're considering a project in which we have expected cash flows for 2021 - 2023, have assigned a discount rate of 13% and somehow know we can sell the project for an amount at the end of 2023 as indicated in the following table. The equation this example uses is the NPV equation: PV_{Cash} Flows $- PV_{Cost} = NPV$. We've included both the benefits (cash flows) and costs in the same equation resulting in an NPV of \$0.

Period	Cash Flow	Sale Amount	Sum	Discounted Cash Flow	Running Total of
					Discounted Cash Flows
2020	-1382		-1382	-1382	-1382
2021	200		200	176.99	-1205.22
2022	300		300	234.94	-970.27
2023	400	1000	1400	970.27	0.00

Does this mean this project isn't expected to make any money? No, it means the project is expected to make the discount rate, no more and no less. After all, the project cost us \$1,382 and we received cash flows and sale proceeds totaling \$1,900 (200+300+400+1,000) and anyone would agree we made \$518 in profits (1900 -1382), right? This is the *nominal profit* or the *accounting profit*.

An economist will look at this and tell us we have a \$0 *economic profit* because the economist has taken into account the opportunity cost of the capital we committed to the project... the discount rate. When we did this and calculated the present value of the expected future cash flows, include the sale proceeds and subtracted the present value of the cost, the resulting NPV = 0. So... NPV is synonymous with *economic profit*.
